

## Q1. Distributed Systems with Examples

A distributed system is a collection of independent computers that appear as a single coherent system. These system consist of multiple autonomous computational entities connected through a network that work together to achieve common goals.

### KEY CHARACTERISTICS

- (1) Heterogeneity - Distributed systems can consist of various hardware and software components from different vendors that work together effectively.
- (2) Scalability - These systems can grow easily by adding more computers, allowing them to handle increased workloads and accommodate business growth.
- (3) Fault Tolerance - If one computer fails, others can continue working, ensuring system reliability and continuous operation.
- (4) Concurrency - Multiple processes can execute simultaneously across different nodes, improving overall system performance.
- (5) Transparency - The complexity of the distributed nature is hidden from users, making the system appear as a single entity.
- (6) Resource Sharing - Hardware, software and data resources are shared among multiple computers in network.

### Examples -

- (1) Client-server Systems - Web applications where browsers request services from web servers that provide resources and process requests.
- (2) Peer-to-peer Systems - Each nodes act as both client and server, sharing resources directly without central co-ordination. BitTorrent file-sharing networks exemplify this architecture.
- (3) Grid Computing System - Multiple computers are connected to form a virtual supercomputer, commonly used for scientific research requiring massive computational power.

- (4) Cloud Computing System - Provide on-demand access to shared computing resources like servers, storage and applications through services like AWS, Azure and Google Cloud Platform.

## Q2. System Models in Distributed Systems

System Models provide frameworks for understanding and designing distributed systems by describing their structure, behaviour and properties.

### ARCHITECTURAL MODELS

- (1) Layered Architecture - Organizes the system into multiple layers where each layer provides specific services and communicates with adjacent layers using well-defined protocols.
- (2) Object-based architecture - Components are organized as objects that interact through method invocations, promoting modularity and reusability.
- (3) Event-based Architecture - Components interact by sending and responding to events rather than direct requests, commonly used in IoT systems and real-time applications.
- (4) Client-server Model - Centralized approach where clients initiate service requests and server respond by providing those services using protocols like TCP/IP and HTTP.
- (5) Microservices Model - Complex applications are decomposed into small, independent services that perform specific functions and communicate over networks.

### FUNDAMENTAL MODELS

- (1) Interaction Model - Deals with communication details among components, including timing, performance and synchronous versus asynchronous communication patterns.
- (2) Failure Model - Describes different types of failures that can occur in distributed systems, including crash failures, omission failures, Byzantine failures.
- (3) Security Model - Addresses security concerns including authentication, authorization, data integrity, protection against malicious attacks in distributed environments.

### Q3. Time and Global States - Logical Checks

Time Coordination is crucial in distributed systems since there's no global physical clock. Logical clocks provide mechanisms to order events and maintain consistency across distributed nodes.

#### Lamport's logical clock:-

Lamport clock are event counters that increment with every interaction, providing a partial ordering of events.

#### Algorithm:-

- Each process maintains a logical clock  $LC_i$
- Before executing an event, increment  $LC_i = LC_i + 1$
- When sending a message, include current  $LC_i$  value
- Upon receiving a message with timestamp  $LC_j$ , update  $LC_i = \max(LC_i, LC_j) + 1$

#### Properties:-

Lamport clocks ensure that if events  $a$  happened - before event  $b$ , then  $LC(a) < LC(b)$ , but the converse isn't necessarily true.

|    |    |     |
|----|----|-----|
| 0  | 0  | 0   |
| 6  | 8  | 10  |
| 12 | 16 | 20  |
| 18 | 24 | 30  |
| 24 | 32 | 40  |
| 30 | 40 | 50  |
| 36 | 48 | 60  |
| 42 | 56 | 70  |
| 48 | 64 | 80  |
| 54 | 72 | 90  |
| 60 | 80 | 100 |

(a)

Three processes each with its own clock. The clock run at different Rates

|    |    |     |
|----|----|-----|
| 0  | 0  | 0   |
| 6  | 8  | 10  |
| 12 | 16 | 20  |
| 18 | 24 | 30  |
| 24 | 32 | 40  |
| 30 | 40 | 50  |
| 36 | 48 | 60  |
| 42 | 61 | 70  |
| 48 | 69 | 80  |
| 54 | 77 | 90  |
| 60 | 85 | 100 |

(b)

Lamport's algorithm corrects the clocks

### LAMPORT'S ALGORITHM

Vector Clocks-

Vector clocks use an array of integers where each element corresponds to a process in the system.

Algorithm-

- Each process  $P_i$  maintain vector  $VC[1..n]$  where  $n$  is the number of processes.
- Before local event :  $VC_i[i] = VC_i[i] + 1$
- When sending message : include current  $VC_i$
- Upon receiving message with  $VC_j$  :  $VC_i[k] = \max(VC_i[k], VC_j[k])$  for all  $k$ , then  $VC_i[i] = VC_i[i] + 1$

Advantages : Vector clocks can detect causal relationships and concurrent events reliably, providing stronger ordering guarantees than Lamport clocks.

Limitation - Higher overhead (vector size grows with number of processes)

Q4. Consensus Problem and Distributed Mutual Exclusion

The consensus problem requires multiple processes to agree on a common value or decision despite potential failures. It's fundamental for maintaining consistency in distributed systems.

Challenges in Achieving Consensus

- (1) Network Partitions - Communication failures can split the system into isolated groups.
- (2) Process failures - Nodes may crash or behave maliciously

- (3) Asynchronous Communication - Message delays and ordering issues complicate coordination
- (4) Incomplete Information - Processes have limited knowledge of global system state.

### Distributed Mutual Exclusion Algorithms

- (1) Token-based approach - A unique token circulates among processes, only the token holder can access the critical section
- (2) Non-token based (Ricart - Agrawala Algorithm) uses timestamps and voting mechanisms where process requests permission from all others before entering critical sections.
- (3) Quorum-based approach - Process must obtain permission from a majority of nodes before accessing shared resources.
- (4) Requirements - All algorithms that must ensure mutual exclusion (only one process in critical section), progress (eventual access), and fairness (bounded waiting) while avoiding deadlocks.
- (5) Implementation Challenges - Message passing is the sole communication mechanism, requiring careful handling of message delays and potential failures.
